- A high energy *ep* collider and motivation
- Proton-driven plasma wakefield acceleration
- AWAKE experiment at CERN
- An *ep* collider based on PDPWA
- Summary

# A high energy $ep$ collider

A high energy  $ep$  collider complements the  $pp$  programme from the LHC (also a future  $e^+e^-$  collider)

- Deep inelastic scattering and parton distribution functions
- Measurements of Higgs production
- Precise extractions of  $\alpha_s$  and search for new physics
- $eA$  physics

See LHeC talks for further motivation

Describe a mechanism (particularly) applicable to accelerating electrons to high energies

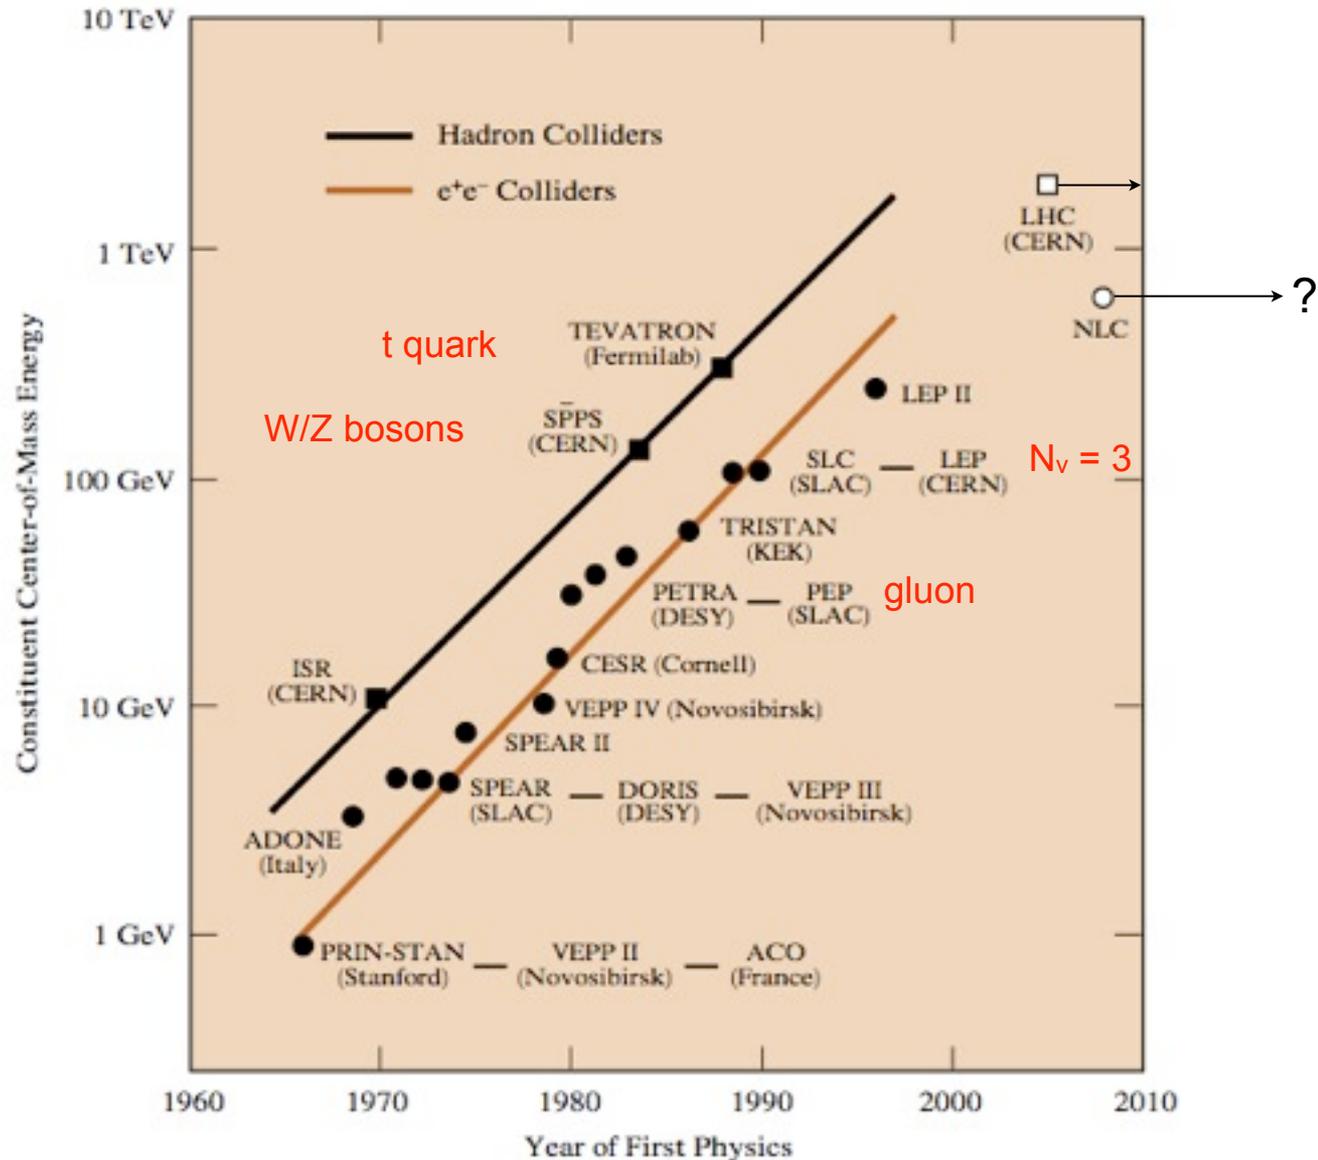

# Collider history

Limitations in RF acceleration

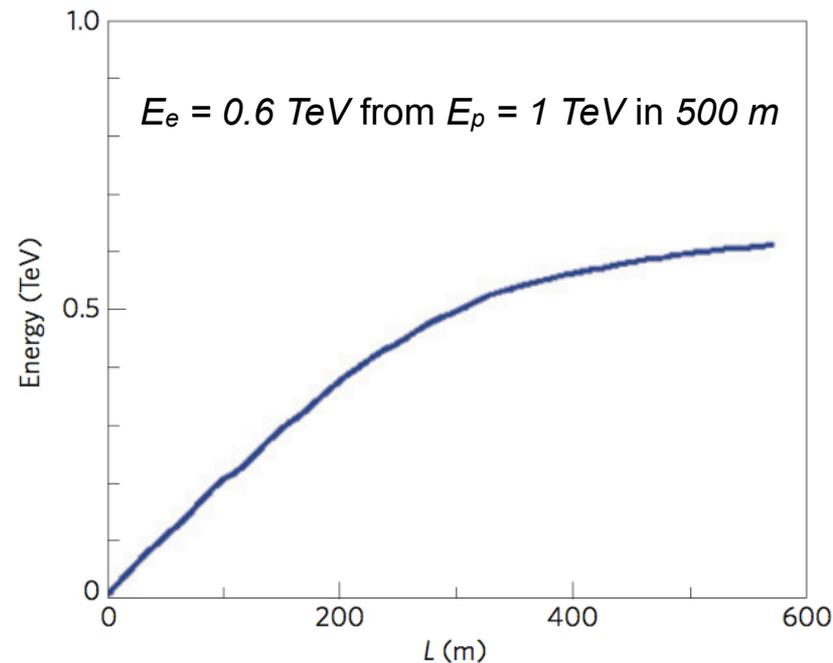

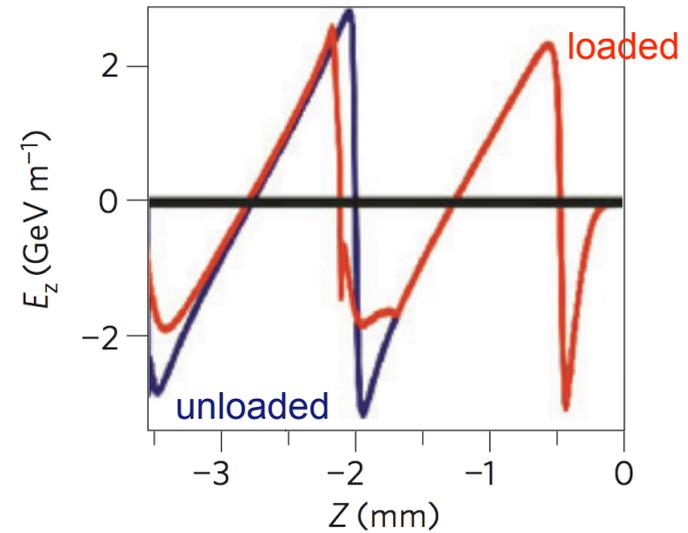

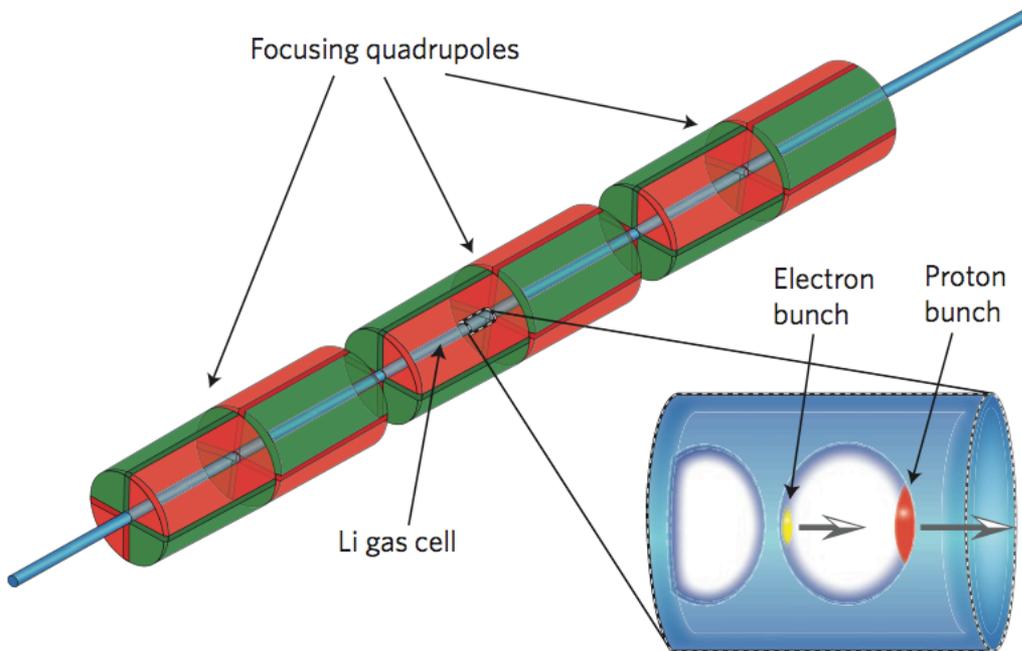

Principle holds for  $ep$  colliders

Can we develop new technologies ?

Plasma wakefield acceleration has up to  $\sim 100 \text{ GV/m}$

# PDPWA concept\*

- Electrons ‘sucked in’ by proton bunch
- Continue across axis creating a depletion region
- Transverse electric fields focus witness bunch
- Maximum accelerating gradient of  $3 \text{ GV/m}$

**Abstract.** New acceleration technology is mandatory for the future elucidation of fundamental particles and their interactions. A promising approach is to exploit the properties of plasmas. Past research has focused on creating large-amplitude plasma waves by injecting an intense laser pulse or an electron bunch into the plasma. However, the maximum energy gain of electrons accelerated in a single plasma stage is limited by the energy of the driver. Proton bunches are the most promising drivers of wakefields to accelerate electrons to the TeV energy scale in a single stage. An experimental program at CERN – the AWAKE experiment – has been launched to study in detail the important physical processes and to demonstrate the power of proton-driven plasma wakefield acceleration. Here we review the physical principles and some experimental considerations for a future proton-driven plasma wakefield accelerator.

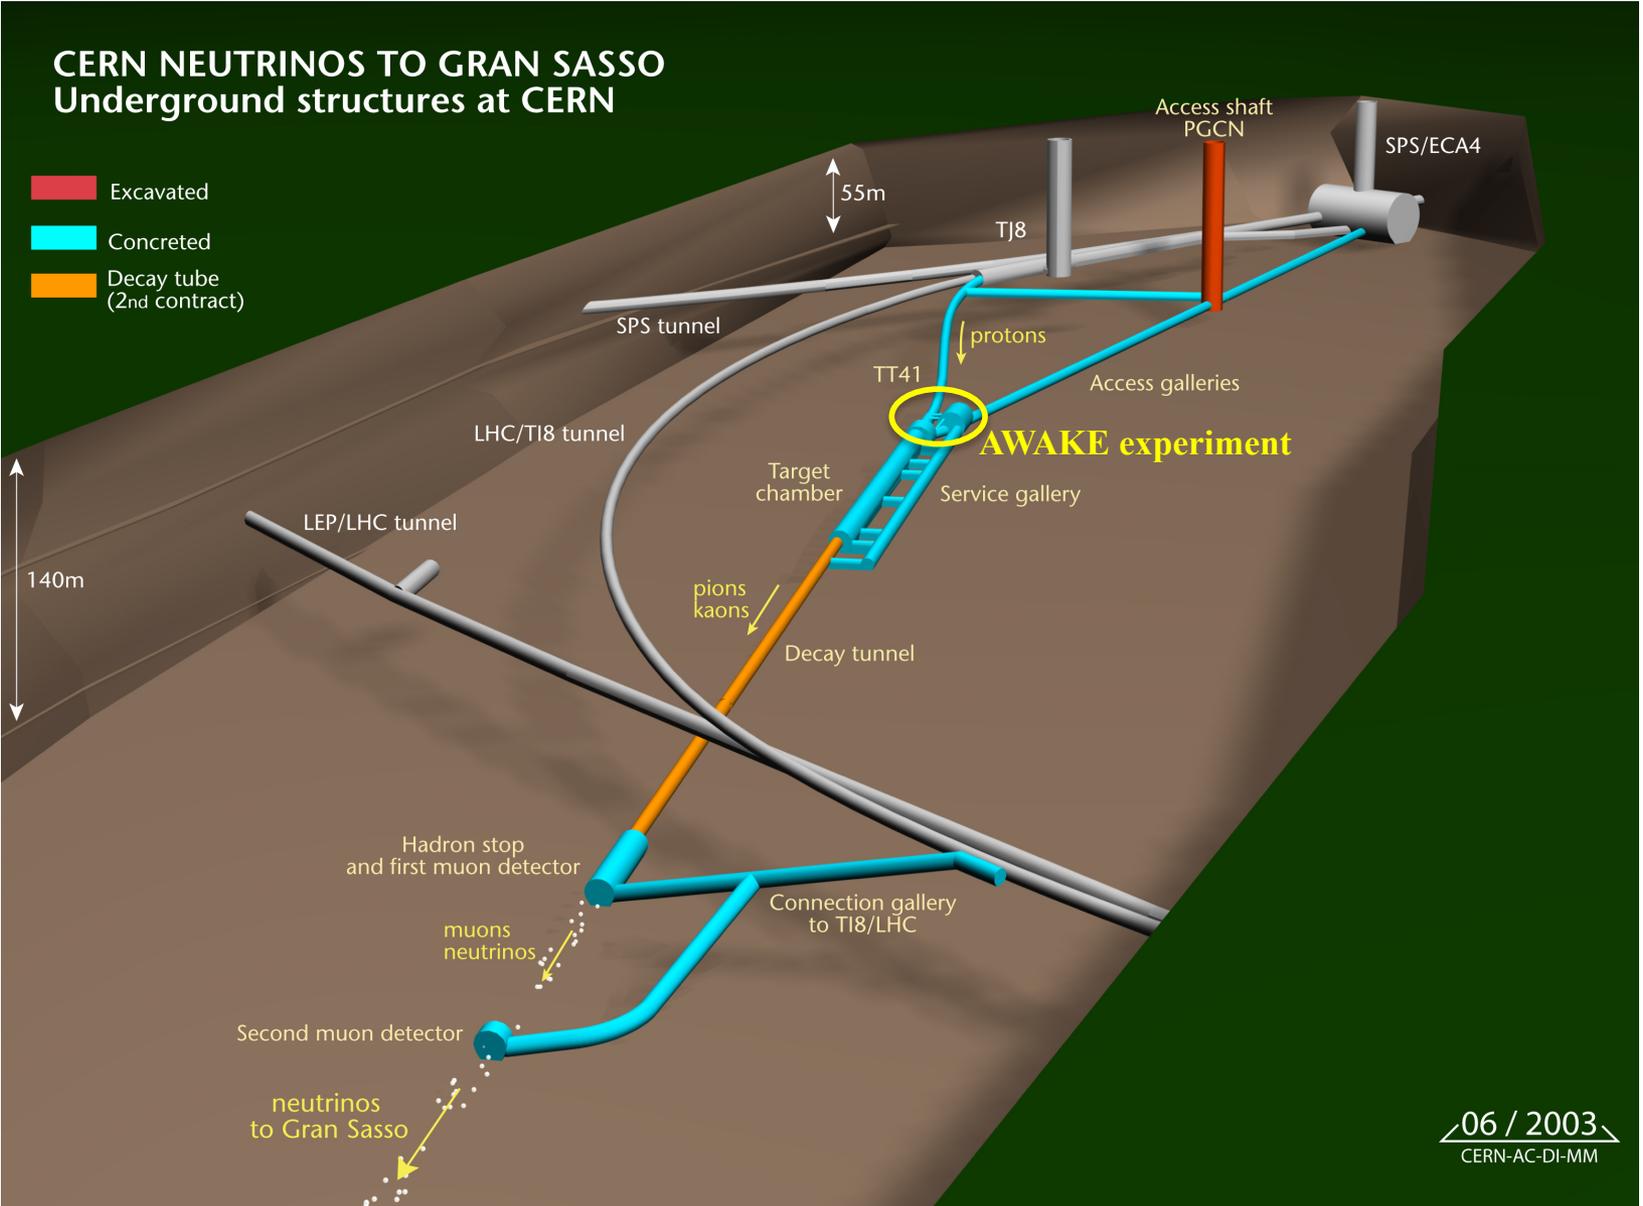

arXiv:1401.4823, to appear in Plasma Phys. Control. Fusion

# Self-modulation and electron acceleration

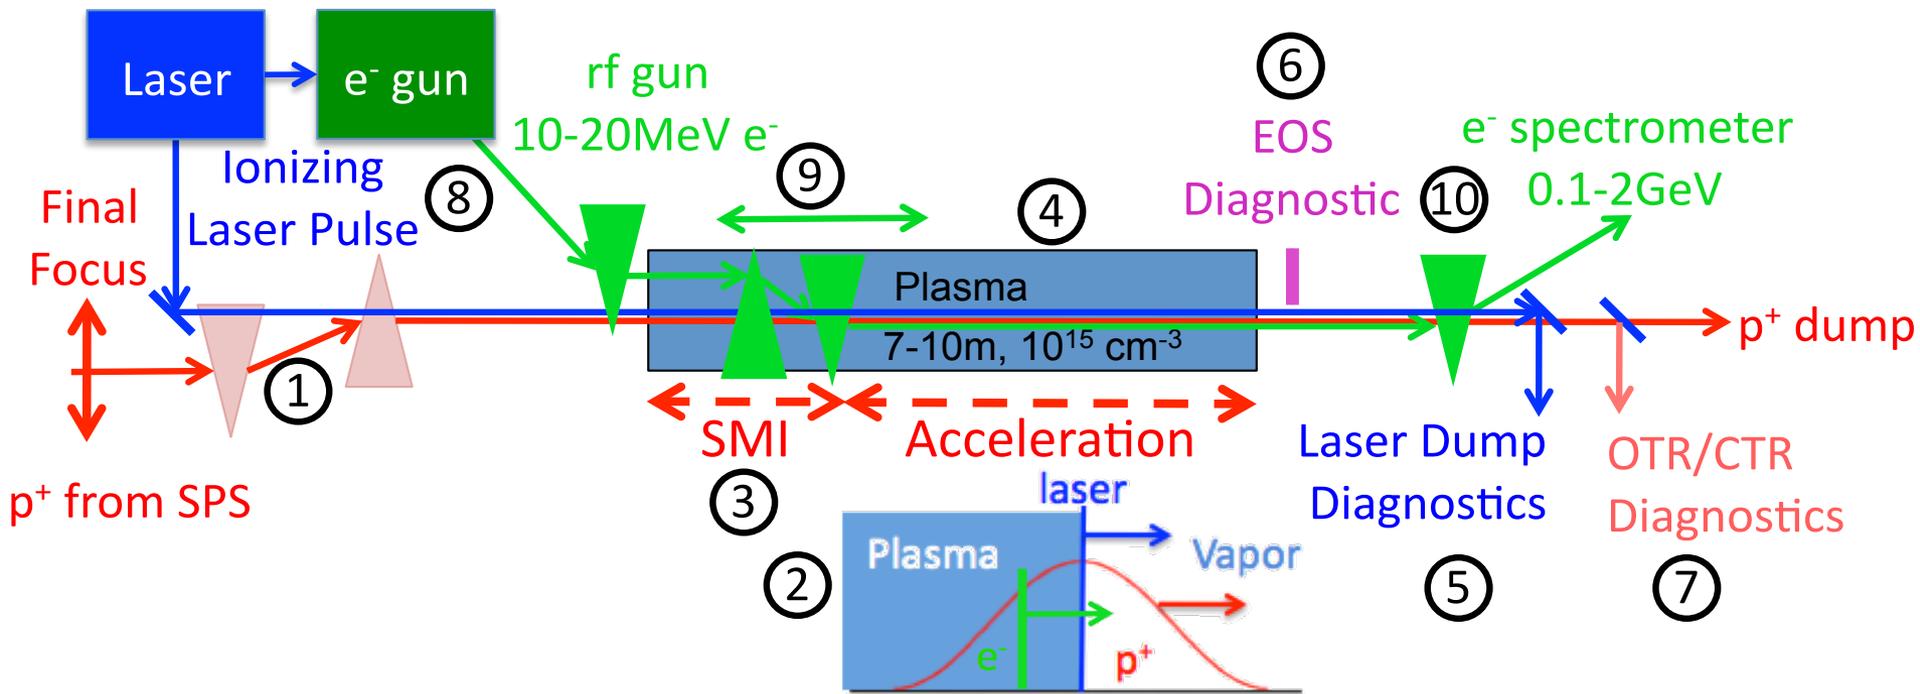

Proton bunches are long  
Rely on micro-bunching

# CNGS facility at CERN

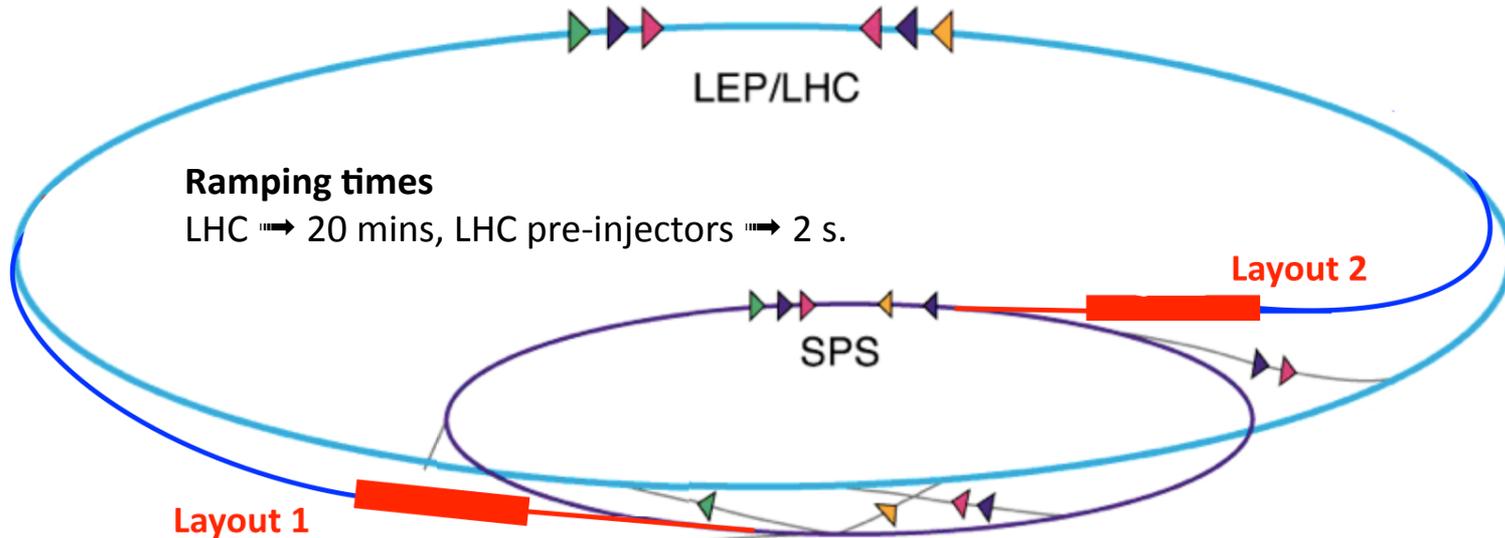

# AWAKE experiment and programme

- Demonstrate self-modulation effect of a long proton bunch and realise  $> 1$  GeV electron energy gain in 10 m plasma
- Develop and test diagnostic equipment for first and later experiments
- Benchmark simulations against data
- Provide input for future experiment of  $\sim 100$  GeV energy gain in  $\sim 100$  m plasma

Data taking to start 2016, first electron acceleration in 2018

# An ep collider, example layouts

- SPS protons excite plasma during LHC ramping. Gradients  $\sim 1$  GV/m, accelerate  $e^-$  to 100 GeV in 170 m plasma.
- Parasitic ep collisions with LHC pp running
- Utilisation of CERN infrastructure: prospects of cost-effective collider
- Basic sub-systems: transfer and matching of protons to plasma section; electron source; plasma section; beam delivery final focus; beam dumping / recycling

# Issues

## Phase slippage

The phase slippage (or dephasing) is a limiting factor of proton-driven plasma wakefield acceleration. Have different particles travelling at different velocities; dephasing ?

Velocity of wakefield is the velocity of the proton driver,  $\gamma_p$

Velocity of the accelerating electrons,  $\gamma_e$ , can soon be greater than  $\gamma_p$  and so electrons overrun the wakefield !

- Can get  $\sim 4 \text{ km}$  for the LHC beam (plasma density dependent) and  $E_e \sim 1 \text{ TeV}$
- Can get  $170 \text{ m}$  for the SPS beam and  $E_e \sim 100 \text{ GeV}$

## Proton beam propagation

Will the proton beam propagate without spreading over hundreds of metres or kilometres of plasma ?

- Transverse focusing can be achieved with external quadrupole magnets or the wakefields themselves
- Large relative momentum spreads should not be an issue for long stages as long as the drive beam is ultra relativistic

# Issues

## Electron-plasma interactions

Witness particles can scatter from plasma ions and plasma electrons

Previous studies from damping rings and for ILC

Model being developed using plasma simulation code and GEANT

## Positron acceleration

Clear issue for  $e^+e^-$  collisions, but also for  $e^+$  running at and  $ep$  collider

Simulations show can accelerate witness protons

At high energies, positron acceleration should be feasible too

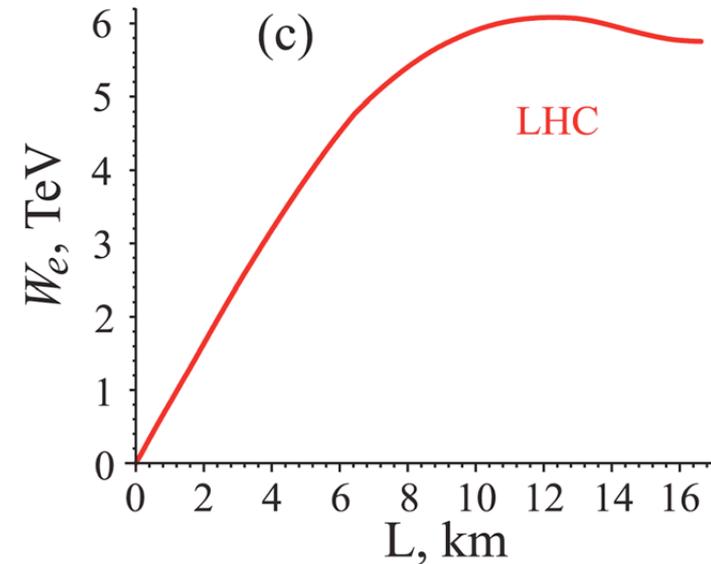

# An ep collider, basic parameters

$$\sqrt{s} = 2\sqrt{E_e E_p} = 1.67 \text{ TeV}$$

$$\mathcal{L}_{ep} = \frac{1}{4\pi} \frac{P_e N_p \gamma_p}{E_e \epsilon_p^N \beta_p^*}, \quad P_e = N_e E_e n_b f_{rep}$$

$$N_e = 1.15 \times 10^{10}, E_e = 100 \text{ GeV}, n_b = 288, f_{rep} = 15$$

$$\mathcal{L}_{ep} = 1 \times 10^{30} \text{ cm}^{-2}\text{s}^{-1}$$

A. Caldwell & K. Lotov, Phys. Plasmas **18** (2011) 103101

Significantly lower than current LHeC designs.

Can the electron bunch intensity and repetition rate be improved ?

### 1 Introduction

The main focus of the particle physics community, when considering future accelerators, has been on high luminosity colliders since  $s$ -channel cross sections scale as  $1/s$ , with  $s$  the square of the center-of-mass energy. This focus has led to ILC, CLIC or Muon Collider parameter sets requiring luminosities in excess of  $10^{34} \text{ cm}^{-2} \text{ s}^{-1}$  for center-of-mass energies beyond 1 TeV. This requirement on the luminosity then leads to very demanding requirements on parameters such as beam sizes at the interaction point, repetition rate, etc., and huge power requirements. The former will be difficult to achieve technologically, while the latter will be very hard to justify in an age of diminishing energy resources and increasing energy costs.

Focus on lepton colliders. Should can consider further and for  $ep$  physics too.

# Summary

- Proton-driven plasma wakefield acceleration can be used to accelerate electrons to the energy frontier in a single stage
- AWAKE will demonstrate proton-driven plasma wakefield acceleration for the first time
  - Demonstration of self-modulation
  - Acceleration of electrons
- AWAKE experiment will inform future possibilities for high energy colliders in  $ep$  and  $e^+e^-$
- Such an  $ep$  collider can reach centre-of-mass energy  $1.67\text{ TeV}$  and luminosity  $10^{30}\text{ cm}^{-2}\text{s}^{-1}$ 
  - Consider schemes to increase electron bunch intensity and repetition rate
  - Consider physics possibilities for a high energy, low luminosity  $ep$  collider
